Parking Lot Recharge Design for easterly portion of site

**#2 Broadway
Lynnfield, Massachusetts**

August 8, 2019

Purpose:

The purpose of this analysis is to design appropriately sized sub-surface recharge area for storm events up to and including the 100-year storm event for the easterly portion of the proposed parking lot adjacent to Broadway (Newburyport Turnpike - Route 1) in order to compensate for the overage in impervious area from the previously approved plan submitted by Hancock Associates, revised through July 14, 2016.

Introduction:

Monastiero Consulting Services, LLC is planning to construct a 68-unit condominium development in a single four (4) story building. The existing site has remnants of a concrete foundation and paved parking areas which are currently overgrown. There are also areas comprised of fill and gravel that were part of former site development. The proposal is to redevelop the site with the construction of the condominium building, paved surface and subsurface parking areas, walkways, landscaping, sewer, water and a new drainage system for treatment of stormwater runoff. Stormwater will be managed through a series of drainage structures and basins that have been designed and approved in accordance with local state and federal regulations. Soil disturbing activities will include: razing existing foundations and parking areas; installing a stabilized construction exit; installing erosion and sediment controls; grading; excavation for the subsurface parking and stormwater treatment structures, utilities, building foundations; construction of parking areas; and preparation for final seeding, mulching, and landscaping.

As mentioned above, the proposed overage in impervious area from the approved plans is approximately 1,332 s.f., In order to be conservative in our design, we have designed the subsurface system to intercept and exfiltrate 2,000 s.f. of impervious area in order to mitigate the post-development runoff rates for the 2, 10- & 100-year storm events.

Existing Condition Soils Analysis:

In order to model the runoff parameters for both the existing and proposed watershed parameters, the parent soils on site were mapped using the Web Soil Survey (WSS) made available on the United States Department of Agriculture (USDA) National Resources Conservation Service (NRCS) website. The WSS provides vital soil data and information such as Hydrologic Soil Group (HSG) which is then input into a mathematical model to generate runoff curve numbers.

The user inputs the soil cover type as well as the hydrologic soil group to generate a weighted curve number (CN) and also uses the topography of the land to generate a time of concentration (Tc) from which the stormwater runoff rate as well as volume may be calculated for a certain watershed for comparison.

The WSS the soil in this portion of the project as Map Unit Symbol, 602, Urban land with no Hydrologic Soil Group rating. The area in the westerly portion of the site is listed as Map Symbol 102C, Chatfield-Hollis-Rock outcrop complex, 0 to 15 percent slopes with a Hydrologic Soil Group of "B".

On August 6, 2019, Williams & Sparages excavated and observed a test pit in the location for the proposed parking lot recharge system to confirm the soil texture currently in place. The material observed was comprised of approximately 36" of firm in place, sandy-loam fill over a looser, weak structure sandy-loam fill material down to a depth of 120. There was no groundwater encountered, no redox and no weeping observed in the test pit. Based on these results, we have assumed that the soils in the area of the proposed system will also behave with a hydrologic soil group of "B".

The proposed design of the parking lot recharge system will require the excavation and removal of the existing material within the proposed bed area down to the specified level and replaced with suitable backfill that meets the requirements set forth in the Cultec Specifications.

We have assumed a design infiltration rate through the bottom of the system equaling 1.02 inches per hour as found on Table 2-1 of the Hydrology Handbook for Conservation Commissioners, March 2002 for sandy loams.

Stormwater Modeling Methodology:

The mathematical model used in this analysis was provided using the HydroCAD 10.00-25 Version developed by HydroCAD Software Solutions LLC. HydroCAD is a program that is used to model the hydrology and hydraulics of stormwater runoff and is based largely on programs and techniques developed by the Soil Conservation Service (SCS) now known as the NRCS, specifically TR-20 and TR-55 as well as other hydraulic calculation methods.

HydroCAD allows the user, for a given rainfall event, to generate runoff hydrographs for single or multiple watersheds and is used to determine if a given drainage system is adequate under the desired conditions as well as to predict flooding or other impacts at specified locations such as erosion. In this analysis a 24-hour Type III distribution for using the Rainfall Data for Essex County using the information presented in the Adjusted Technical Paper 40 (TP-40) Design Storms.

Three (3) design storm events were analyzed and the results presented in the tables that follow for the ten (10) year, the twenty-five (25) year and one-hundred (100) year storm events for comparison.

Existing Condition Watershed:

Not Applicable

Proposed Condition Watershed:

The curve number for the pavement area to be captured was selected as 98 and a time of concentration of 6 minutes was assumed for the catchment area. A schematic of the mathematical model as well as the results of the calculations for the 2-year, 10-year, and 100-year, Type III, 24-hour storm events are included in this report.

In order to pre-treat the stormwater runoff from the parking area, we have specified a deep-sump catch basin with "The Eliminator" catch basin trap or approved equal as well as a Sediment & Oil Separator (SOS) before discharging to the Cultec System as shown on the revised plan.

Pretreatment: 44% TSS Removal (25% for CB; 25% for SOS)

Total Treatment: 85% TSS Removal (80% for Cultec System w/Pretreatment; 25% SOS)

Conclusion:

As can be seen by examining the following performance summary table for the parking lot recharge system, the design is effective for mitigating the peak flow rates of runoff from the selected paved area for the 2, 10, & 100-year storm events in accordance with the originally approved drainage analysis for the project.

Proposed Parking Lot Recharge System (HydroCAD 1P)

The soil surveys that comprise your AOI were mapped at 1:15,800.

Warning: Soil Map may not be valid at this scale.

Enlargement of maps beyond the scale of mapping can cause misunderstanding of the detail of mapping and accuracy of soil line placement. The maps do not show the small areas of contrasting soils that could have been shown at a more detailed scale.

Please rely on the bar scale on each map sheet for map measurements.

Source of Map: Natural Resources Conservation Service
 Web Soil Survey URL:
 Coordinate System: Web Mercator (EPSG:3857)

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: Essex County, Massachusetts, Southern Part
 Survey Area Data: Version 15, Sep 7, 2018

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: Aug 10, 2014—Aug 25, 2014

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

Hydrologic Soil Group

Map unit symbol	Map unit name	Rating	Acres in AOI	Percent of AOI
102C	Chatfield-Hollis-Rock outcrop complex, 0 to 15 percent slopes	B	3.4	24.4%
602	Urban land		10.6	75.6%
Totals for Area of Interest			14.1	100.0%

Description

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The soils in the United States are assigned to four groups (A, B, C, and D) and three dual classes (A/D, B/D, and C/D). The groups are defined as follows:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas. Only the soils that in their natural condition are in group D are assigned to dual classes.
